    def numLinks(self):
        summ = 0
        for n in self.nodes:
135             summ = summ + len(self.getNode(n).nodelist)
        return summ / 2

```

(b) Listing 1 shows source code.

(c) Listing 1 shows source code.

(d) The number of cliques stays approximately the same independent of the time step because approximately the same amount of edges are added which are removed as shown in figure 1, table 4 and table 4. The amount of cliques of size 3 increases rather than the one of larger cliques because a less edges added may result in a small clique.

clique size	number of cliques before evolution	number of cliques after evolution
3	294	300
4	33	33
5	3	3

Table 1: Number of cliques of size 3, 4 and 5 at the beginning and after letting it evolve for 100 time steps

clique size	number of cliques before evolution	number of cliques after evolution
3	294	327
4	33	27
5	3	3

Table 2: Number of cliques of size 3, 4 and 5 at the beginning and after letting it evolve for 1000 time steps

(e) The goal of randomising networks this way is to create random permutations of a network. In this way the behaviour of similar networks may be studied and the networks quality may be rated.

Listing 2 shows source code.

clique size i	$p_i$
3	0.38
4	0.27
5	1.0

Table 3: Number of randomised networks in which the number of cliques is at least as high as in the original network divided by the number of randomised networks for each clique size

## Exercise 5.2: Annotations in Protein Protein Interaction Networks

- (a) Implemented in PPIGONetwork.py, see Listing 4
- (b) Required information provided in table 4

Table 4: Results for exercise 5.2 b

Task	Result
total number of proteins and interactions in the network	17087
total number of unique annotations in the network	275472
total number and percentage of proteins without any annotation	2334 (13.6595%)
smallest number of annotations per protein	0
average number of annotations per protein	7.013
highest number of annotations per protein	184
smallest number of associated proteins per annotation	1
average number of associated proteins per annotation	7.013
highest number of associated proteins per annotation	1519

- (c) In table 5, we see the five most and least annotated GO terms. We see that the most annotated GO terms are all involved in crucial biological processes for cell viability. In this way, we have important transcription factors, which regulate the different expression levels. Additionally, we have one GO term encoding signal transduction, which is also important for cell communication, apoptosis, etc. Further, the GO terms are relatively unspecific, so they do not describe just one specific process, - this fewer information content leads to a high number of annotations. Therefore it is no surprise that these GO terms are high annotated. In contrast, the least annotated GO terms describe various, precise biological processes. Therefore they can only be assigned to a specific subset of human proteins. Therefore we see only a few annotations of them. So they are less common but have a higher information content than the most annotated proteins GO terms.
- (d) Not implemented
- (e) Not implemented
- (f) Listing 4 shows source code.
